

Week 8 Report

The data set I will be going over is Rice, P. C., & Paterson, A. L. (1985). Cave art and bones: exploring the interrelationships. *American Anthropologist*, 87(1), 94-100.

This data has (n=50) observations. This data also has four variables, including region, bone abundance, bone art count, and Taxa. Region means where the fauna was located and found. Bone abundance means how much of a certain type of fauna remains from a certain animal. Bone art means the quantity of the bone that was used or created into pieces of art of each type of remains. Taxa meaning the type of faunal remains.

Table One: (Counts)

TAXA	BoneArt_Count	Bone Abundance
BOVINES	386	223
DEER	79	150
HORSE	297	266
IBEX	97	54
REINDEER	70	289

Taxa Tables:

Questions:

- What is the relationship between amounts of art and amounts of animal bone at these Paleolithic sites?

The relationship between the amount of art and the amount of animal bone at all these paleolithic sites is a positive correlation of the two, with the correlation amount being 0.357443, meaning any amount of bone from faunal remains that is found from this period is significantly correlated with bone art and the abundance of bones.

- How does this relationship vary for specific types of animals?

These relationships vary typically in a positive manner, where the Bovines' results were 0.3646652, the results for deer were 0.6295011, the results for horse were 0.1397397, the results for Ibex were 0.3486233, and the Reindeer results were 0.6889846. All these correlation test results were positive, where the highest positive correlation was the Reindeer with art and abundance correlation, and the lowest positive correlation was the horse's correlation, even though it was still positive.

- *What hypotheses about the purpose of cave art are supported by these relationships?*

I hypothesized that Paleolithic people highly valued reindeer and other deer remains, as evidenced by art made from their bones, rather than other faunal remains. Another Hypothesis is that even though there is a greater abundance of horse bones than the rest of the remains of other taxa, they were more likely hunted more often than the other taxa and were seen as less valuable in spiritual or artistic terms with bone materials.
